

Supplemental Figure 1. Scatter plots demonstrate that associations between FA and decoding are unlikely to be driven by gender differences in full term and preterm groups. Scatter plots from Figures 2 and 3 are repeated here only for those tracts (aSLF-L, CST-L, CST-R) found to demonstrate significant associations with decoding in both full term (a-c) and preterm groups (a1-c1). Scatter plots are the same as those reported in Figures 2a,d,e and 3a,d,e and now include symbols (diamonds or triangles) to denote gender (male or female, respectively). (FA = fractional anisotropy; aSLF = anterior Superior Longitudinal Fasciculus; CST = corticospinal tract; L= left; R= right).
